

## **TRANSPARENCY ADAPTER WITH LIGHT TABLE**

### **FIELD OF THE INVENTION**

The present invention relates generally to light tables used to view  
5 transparent media and transparency adapters used with scanners, and more  
specifically to a combination transparency adapter and light table for use  
with a scanner.

### **BACKGROUND OF THE INVENTION**

10 Scanning transparent media such as photographic slides, negatives,  
and the like, requires several activities. First, the transparent media is  
viewed on a light table or, if a light table is not available, by simply holding  
the transparent media up to a light source such as a ceiling light or window  
in order to select the correct negative, frame, etc. The selected transparent  
15 media must then be oriented correctly on a scanner platen. Since the  
scanner platen is typically not illuminated until scanning begins, any  
transparent media placed on the scanner platen is not viewable thereon.  
Thus, the transparent media must be oriented "blindly" on the scanner  
platen, i.e., the user not only must remember the orientation of the  
20 transparent media as it was viewed in the light, but he or she must then  
transfer the correct orientation of the transparent media to the scanner  
platen. With some scanner systems, a removable template may be  
provided which is adapted to hold and align transparencies on the scanner

platen. While a light table or the like may be utilized to correctly orient the transparent media within a template, the template itself must then be “blindly” oriented on the scanner.

In order to scan transparent media on a flatbed scanner, a transparency adapter must be used. A conventional transparency adapter includes a light source which projects light through the transparent media and through the scanner platen, so that an image of the transparent media may be captured by a sensor, typically a charge-coupled device (CCD), in the scanner. Thus, not only does the scanner have its own light source, but also both the transparency adapter and the separate light table each have their own light source. While transparent media is more easily viewed with a light table than with a secondary source of light such as a ceiling light or a window, providing a separate light table along with a transparency adapter, each with its own light source, is costly and inefficient.

### **SUMMARY OF THE INVENTION**

The present invention is directed to a transparency adapter for use with a scanner comprising a scanner light source, a scanner platen and a scanner lid. The transparency adapter comprises a light table comprising a stationary light source separate from the scanner light source. The stationary light source comprises a light table operating state for illuminating transparent media for viewing and a transparency adapter operating state for illuminating transparent media while it is being scanned by the scanner, thereby creating a scanned image of the transparent media, the scanned

image having an output orientation. The transparency adapter further comprises at least one mounting device on the light table to hold the transparent media in an input orientation during the light table operating state.

5           The present invention is also directed to a scanner comprising a scanner light source, a scanner platen, a scanner lid, and a transparency adapter within the scanner lid. The transparency adapter comprises a light  
10           table comprising a stationary light source separate from the scanner light source. The stationary light source comprises a light table operating state for illuminating transparent media for viewing and a transparency adapter  
15           operating state for illuminating transparent media while it is being scanned by the scanner, thereby creating a scanned image of the transparent media, the scanned image having an output orientation. The transparency adapter also comprises at least one mounting device to hold the transparent media in an input orientation during the light table operating state.

20           The present invention is also directed to a method for scanning transparent media using a scanner comprising a scanner light source and a scanner platen. The method comprises placing the transparent media on a transparency adapter having a stationary light source that is separate from the scanner light source; utilizing the transparency adapter to orient the  
25           transparent media to an input orientation; directly transferring the input orientation to the scanner platen by closing the transparency adapter; and scanning the transparent media to obtain a scanned image with an output

orientation while the stationary light source illuminates the transparent media, wherein the output orientation is the same as the input orientation.

### **BRIEF DESCRIPTION OF THE DRAWINGS**

5            Fig. 1 is a perspective view of a first exemplary embodiment of a transparency adapter with a light table as an accessory to a standard scanner.

10           Fig. 2 is a perspective view of a second exemplary embodiment of the transparency adapter with a light table as an integrated component in a scanner lid.

            Fig. 3 is a simplified, partially schematic, cross-sectional view of the transparency adapter with a light table of Figs. 1 or 2 with a first exemplary embodiment of a transparent media mounting device.

15           Fig. 4 is a simplified, partially schematic, cross-sectional view of the transparency adapter with a light table of Figs. 1 or 2 with a second exemplary embodiment of a transparent media mounting device.

            Fig. 5 is a perspective view of a first exemplary template from a transparent media mounting device.

            Fig. 6 is a front view of the template of Fig. 5.

20           Fig. 7 is a front view of a second exemplary template from a transparent media mounting device.

            Fig. 8 is a side view of the transparency adapter with a light table of Fig. 1 in an open/light table operating state.

Fig. 9 is a side view of the transparency adapter with a light table of Fig. 1 in a closed/transparency adapter operating state.

Fig. 10 is a perspective view of the transparency adapter with a light table of Fig. 2 in an open/light table operating state having media in an input orientation.

Fig. 11 is a perspective view of the transparency adapter of Fig. 10 in a closed/transparency adapter operating state and a computer displaying a scanned image of the media in an output orientation.

### **DETAILED DESCRIPTION OF THE INVENTION**

As shown in Figs.1-11, the present invention provides a transparency adapter with a light table 10 (also referred to herein as a "transparency adapter/light table") that allows a user to view and correctly orient transparent media 12 in a "WYSIWYG" ("what you see is what you get") manner prior to scanning. During a light table operating state whereby the transparency adapter/light table 10 is open (Figs. 1, 2, 8 and 10), the transparent media 12 is illuminated by the transparency adapter/light table 10 for viewing. The properly oriented transparent media 12 may then be directly transferred to a scanner platen 102 by simply closing the transparency adapter/light table 10 as discussed in further detail below. During a transparency adapter operating state whereby the transparency adapter/light table 10 is closed (Figs. 9 and 11), the transparent media 12 (not shown in these figures) is illuminated by the transparency adapter/light table 10 for scanning. Thus, the transparency adapter/light table 10 of the present invention may be

used, first, as a light table to orient transparent media 12, and, second, as a transparency adapter to project light onto the transparent media 12 and through the scanner platen 102 while scanning. In a first exemplary embodiment as best shown in Fig. 1, the transparency adapter/light table 10 may be an accessory item used with a conventional scanner 100. In a second exemplary embodiment as best shown in Fig. 2, the transparency adapter/light table 10 may be an integrated component of a scanner lid 104.

Referring to Figs. 1-2, a conventional scanner 100 may be provided having a platen 102, a lid 104, and a housing 106. The scanner housing 106 may house a moveable carriage 110 which includes therein a conventional scanner light source 112 and an image input device (not shown) such as a charge-coupled device (CCD). As shown in Fig. 1, a conventional scanner platen 102 may have a length L1 of, for example, 12 inches and a width W2 of, for example, 9 inches. It will be appreciated, however, that the present invention may be utilized with scanners having platens of various sizes, and that the length and width noted above are merely exemplary. As described in more detail below relative to Figs. 10 and 11, the scanner 100 is adapted to scan transparent media 12, utilizing the transparency adapter/light table 10 while scanning, thereby creating a machine-readable data image of the transparent media 12 to be displayed, printed, stored, or the like.

As shown in Figs. 1-4, the transparency adapter/light table 10 may comprise a front surface 14 and a back surface 16 which may be joined along a first side 18, a second side 20, a third side 22, and a fourth side 24,

creating an internal cavity 28 (Figs. 3 and 4). A platen 26 may be provided on the front surface 14 of the transparency adapter/light table 10. A mounting device 34, described in further detail below, may also be provided to hold the transparent media 12 in place against the platen 26.

5 Transparent media 12 mounted on the mounting device 34 may be illuminated by a stationary light source 30 (Figs. 3 and 4) contained within the internal cavity 28 of the transparency adapter/light table 10. In order to allow light from the stationary light source 30 to pass through the transparent media 12, the transparency adapter/light table platen 26 is  
10 preferably constructed from a translucent material such as textured clear polycarbonate. As described in more detail below relative to the operation of the transparency adapter/light table 10, the stationary light source 30 (Figs. 3 and 4) is physically separate from the light source 112 in the scanner 100 (Figs. 1 and 2) and performs an entirely different function than  
15 that performed by the scanner light source 112.

The stationary light source 30 may comprise, for example, one or more cold cathode, fluorescent lamps 31, 32 as shown in Figs. 3 and 4. The lamps 31, 32 may be powered by and electrically connected to an electrical inverter 38 (shown schematically) connected to a power source (not shown),  
20 which may be the same power source that provides electrical power to the scanner. Such cold cathode, fluorescent lamps are widely available and may be obtained from, for example, Nam Kwong Electric Co. Ltd., 381-389 Sha Tsui Road, Young Ya Industrial Building, 1 C/D, Tsuen Wan, Hong Kong.

As shown in Figs. 3 and 4, the stationary light source 30 may further comprise a reflector 40 positioned adjacent to the lamps 31, 32. The reflector 40 may comprise a light-reflective surface 42 which may be curved as shown in Figs. 3 and 4 so that light from the lamps 31, 32 may be reflected onto the transparency adapter/light table platen 26. Thus, as shown in Fig. 3, the stationary light source 30 may illuminate the platen 26 with direct light (e.g., 44) from the lamps 31, 32 and reflected light (e.g., 45) from the reflector 40. The transparency adapter/light table platen 26 may be adapted to diffuse the light 44, 45 received from the stationary light source 30 and transmit the diffused light (e.g., 46) through the platen 26. As noted above, the platen 26 may be textured to assist in diffusing the light 44, 45.

The mounting device 34, which is adapted to hold the transparent media 12 in place against the platen 26, may have a variety of different configurations depending on the particular application. For example, the mounting device 34 may be adapted to hold several slides (e.g., 13, Figs. 6 and 7) as indicated in Figs. 1 and 2. As another example, when scanning negatives from film stock (e.g., 15, Figs. 6 and 7), the geometry of the mounting device 34 may allow for multiple frames of the film stock to be previewed and scanned. The mounting device 34 may also be adapted to simultaneously hold several different types of transparent media 12 such as slides and film stock. Alternatively, the mounting device 34 may comprise several removable templates 48, Figs. 5-7, that are each adapted to hold varying types of transparent media 12. As shown in Figs. 5-7, the mounting device 34 (and removable template 48, if present) may comprise a plurality

of openings 36 which enable diffused light (e.g., 46, Fig. 5) to pass directly through the transparent media 12 from the stationary light source 30 and platen 26. In this manner, the mounting device 34 (with or without a removable template 48) does not impede or interfere with the passage of light 46 through the transparent media 12.

As best shown in Figs. 3 and 4, a template 48 may be removable from the transparency adapter/light table platen 26 using temporary attachment devices 50, 52. Examples of a first type of temporary attachment device 50, Fig. 3, may be magnets, snaps, hook and loop-type fasteners, or the like. At least one temporary attachment device 50 may be attached to the platen 26 (or, alternatively, to the front surface 14 of the transparency adapter/light table 10), and a corresponding temporary attachment device 50 may be attached to the template 48 at any position, but preferably along the periphery thereof so as not to interfere with the transmission of light through media 12 mounted within the template 48. Another type of temporary attachment device 52, Fig. 4, may be comprised of a plurality of brackets which are adapted to temporarily hold the template 48 in place against the platen 26. The brackets 52 preferably extend across the template 48 only so far as to support the template 48, and should not interfere with the transmission of light through the media 12 within the template 48. The brackets 52 may be positioned adjacent to two or three of the upper edge 54, lower edge 56, and side edges 58, 60 (see Fig. 6) of the template 48 in order to allow a user to slide the template 48 in place against the platen 26. Thus, as shown in Fig. 4, a bracket 52 may be placed adjacent to the side

edges 58, 60 of the template 48, and a bracket (not shown) may also be placed adjacent to the lower edge 56 (Fig. 6) of the template 48 in order to support the template 48 especially when the transparency adapter/light table 10 is open (Figs. 1, 2, 8 and 10). As another example (not shown), brackets may be provided adjacent to the top edge 54 and bottom edge 56 of the template 48, leaving the side edges 58, 60 exposed.

As shown in Figs. 5-7, the template 48 may comprise a plurality of media holding locations 62, 64, 66 adapted to receive media 12 and hold it against the transparency adapter/light table platen 26 (Figs 1 and 2). A first type of media holding location 62 (Figs. 5 and 6) or 64 (Fig. 7) may be provided which is adapted to hold several different types of media 12 such as, for example, slides 13 and film stock 15. Alternatively, as shown in Fig. 7, a second type of media holding location 66 may be provided that is adapted to hold a particular type of media such as, for example, a slide 13. In any embodiment, the media holding locations 62, 64, 66 may be defined by a plurality of support members (e.g., 67, Figs. 5 and 6; 69, Fig. 7). As best shown in Fig. 5, the support members 67 may form channels 68 in order to allow a user to slide media 12 into the media holding locations 62, 64, 66 from at least one side (e.g., top, left or right sides) of each media holding location. For example, as shown in Fig. 6, the media 12 may be slid into a media holding location 62 from either the left side 70 or the right side 71 thereof. As shown in Fig. 7, the media 12 may be slid into a media holding location 64 or 66 from the top side 72 or 74, respectively, thereof. Due to lack to adequate support, the bottom side 76, 77, 78 of a media

holding location 62, 64, 66, respectively, is usually not left completely open. However, it is to be understood that the support members 67, 69 shown in Figs. 5-7 are merely exemplary, and that any support member adapted to securely, removably hold media 12 within a template 48 may be utilized.

5           As best shown in Figs. 1 and 2, the transparency adapter/light table 10 may further comprise at least one controller 80, 82 which may be adapted to control any function of the stationary light source 30 (Figs. 3 and 4). For example, an intensity controller 80 and a state controller 82 may each be operatively connected to the stationary light source 30. The intensity  
10       controller 80 may comprise, for example, a knob, dial, or the like located on a side (e.g., 22) of the transparency adapter/light table 10 which may be manipulated by a user to manually turn the stationary light source on or off and to manually adjust the intensity of the stationary light source 30 as needed for optimal viewing of the transparent media 12. The state controller  
15       82 may be used to disable the intensity controller 80 so that the stationary light source 30 is at a fixed, predetermined intensity while the transparent media 12 is being scanned. Specifically, the state controller 82 may be adapted to sense the position of the transparency adapter/light table 10 (e.g., open or closed), disabling the intensity controller 80 when the  
20       transparency adapter/light table 10 is closed and placing the stationary light source 30 in the transparency adapter operating state. The state controller 82 may also sense when the transparency adapter/light table 10 is open, thereby enabling the intensity controller 80 so that the stationary light source 30 may be turned on or off and the intensity of the stationary light source 30

(now in the light table operating state) may be adjusted as needed. The state controller 82 may comprise, for example, a switch, toggle, proximity sensor, or the like well-known in the art which may be mounted, for example, on the front 14 of the transparency adapter/light table 10. The state controller 82 may be adapted to be automatically toggled when the transparency adapter/light table 10 is opened or closed.

In an alternative embodiment (not shown), the stationary light source may be controlled by software. Thus, instead of (or in addition to) comprising a manually-operable dial, knob, switch, toggle, or the like, the intensity and state controllers may comprise software which allows a user to remotely control, for example, the intensity of the stationary light source for viewing purposes (which may include the ability to remotely turn the stationary light source on or off). When scanning commences, the software may be adapted to automatically override the intensity controller and set the intensity of the stationary light source to an appropriate level for scanning.

In the first exemplary embodiment shown in Figs. 1, 8 and 9, the transparency adapter/light table 10 of the present invention may be an accessory item for use with a conventional scanner 100. The transparency adapter/light table 10 may be pivotally attached by, for example, a pair of hinges 92, 94 to a scanner template 90. The scanner template 90 may be positioned on the scanner platen 102 to align the transparency adapter/light table 10 thereon at any time before, during, or after the light table operating state (but before the transparency adapter operating state commences). To facilitate this alignment and in order to completely cover the scanner platen

102 during scanning, the scanner template width W2 and/or the scanner  
template length L2 (most preferably both) may be the same as the scanner  
width W1 and scanner length L1, respectively. To place the transparency  
adapter/light table 10 in an open or a closed position, the transparency  
5 adapter/light table 10 may be pivotally rotated around axis AA (which is  
defined by the hinges 92, 94) in a rotational direction R. The scanner  
template 90 may have at least one window 96 through which the transparent  
media 12 may be scanned during the transparency adapter operating state.  
A calibration window 98 may also be provided in the scanner template 90 to  
10 allow for sampling of the light emitted from the stationary light source 30  
(Figs. 3 and 4) as is well-known in the art.

In the second exemplary embodiment as shown in Figs. 2, 10 and 11,  
the transparency adapter/light table 10 may be integrally formed within the  
scanner lid 104. The transparency adapter/light table 10 may be  
15 substantially identical to that described above relative to the first exemplary  
embodiment shown in Fig. 1, except that no scanner template (90, Fig. 1) is  
required in this embodiment. Instead, the scanner lid 104 may be pivotally  
attached to the scanner housing 106 with hinges 120, 122 (Fig. 2), or the  
like. To place the transparency adapter/light table 10 in an open or a  
20 closed position, the scanner lid 104 may be pivotally rotated around axis BB  
(which is defined by the hinges 120, 122, Fig. 2) in a rotational direction R.  
The scanner lid 104 in this embodiment may also be removable and  
replaceable with a conventional scanner lid 104 as shown in Fig. 1 so that  
the transparency adapter/light table 10 may be utilized only when needed.

Having described the transparency adapter/light table 10 and its associated components, the operation thereof will now be described. As mentioned above, the invention may alternately be used in a light table operating state (Figs. 1, 2, 8 and 10) and a transparency adapter operating state (Figs. 9 and 11).

With reference to Figs. 1, 2, 8 and 10, in the light table operating state, the transparent media 12 may be placed on the transparency adapter/light table platen 26 within the mounting device 34. The transparency adapter/light table 10 is in a position such as that shown in figures which allows the transparent media 12 to be viewed. In this operating state, the transparent media 12 may be viewed and placed in a desired orientation 130, Fig. 10, which will hereinafter be referred to as the "input orientation". The intensity of light emitted from the stationary light source 30 (Figs. 3 and 4) should be sufficient to see the image contained in the transparent media 12. The intensity controller 80 may be used to adjust (i.e., either brighten or dim) the stationary light source 30 in order to obtain an adequate viewing level.

Once the transparent media 12 has been selected and placed in the desired input orientation 130, the user may close the transparency adapter/light table 10 as shown in Figs. 9 and 11 to invoke a transparency adapter operating state. The state controller 82 may sense the change in transparency adapter/light table 10 position, disabling the intensity controller 80 and invoking the transparency adapter operating state. During this operating state, the stationary light source 30 (Figs. 3 and 4) illuminates the

transparent media 12 while it is being scanned by the scanner 100.

Specifically, the stationary light source 30 projects light through the transparent media 12 and through the scanner platen 102 during scanning of the transparent media 12 so that an image of the transparent media may be captured by the image input device (such as a CCD, not shown) in the scanner 100. The scanning of the illuminated transparent media 12 creates a scanned image 132 having an output orientation 140 as shown in Fig. 11. The scanned image 132 may be comprised of image data that is in machine readable, digital format which may be displayed on a computer monitor 142 as shown. The scanned image 132 can also be utilized for a number of objectives including, but not limited to, manipulation, reproduction, distribution, and storage. The output orientation 140 (Fig. 11) is preferably the same as the input orientation 130 (Fig. 10) so that a user may view and correctly orient transparent media 12 in a "WYSIWYG" ("what you see is what you get") manner prior to scanning.

Accordingly, and with reference to Figs. 10 and 11, the present invention may also be directed to a method for scanning transparent media 12 using a scanner 100 comprising a scanner light source and a scanner platen 102. The first step of the method may involve placing the transparent media 12 on the transparency adapter/light table 10 described above. Next, the transparency adapter/light table 10 is utilized to orient the transparent media 12 to an input orientation 130. Then, the input orientation 130 is directly transferred to the scanner platen 102 by closing the transparency adapter/light table 10. Finally, the transparent media 12 is scanned to

obtain a scanned image 132 with an output orientation 140 while the stationary light source 30 (Figs. 3 and 4) illuminates the transparent media 12. As noted above, the output orientation 140 is preferably the same as the input orientation 130.
